Protocol for Diagnostic Audiological Assessment: Follow-up for Newborn Hearing Screening

It is recommended that infants who are referred from newborn hearing screening for audiological assessment be evaluated using the following protocol before 3 months of age. This protocol was developed by a workgroup comprised of 11 audiologists practicing in Washington, with extensive knowledge and expertise in the screening and diagnosis of hearing loss in newborns and infants. The protocol includes guidance set forth by the Joint Committee on Infant Hearing (JCIH).

1. Risk indicators for use with neonates (birth to 28 days) include: (1) an illness or condition requiring admission of 48 hours or greater to a neonatal intensive care unit (NICU), (2) stigmata or other findings associated with a syndrome known to include a sensorineural and/or conductive hearing loss, (3) family history of permanent childhood sensorineural hearing loss, (4) craniofacial anomalies, including those with morphological abnormalities of the pinna and ear canal, (5) in utero infection such as cytomegalovirus, herpes, toxoplasmosis, or rubella.

In evaluating OAEs, the following stimulus levels are recommended: L1=65 dB SPL & L2=55 dB SPL (DPOAE) or 80 dB pSPL (TEAOE)

- If normal and infant does not meet high-risk criteria and has not failed a prior auditory brainstem response (ABR) ---STOP TESTING. Infants who are not identified with hearing loss, but have one or more risk factors, should be referred before one year of age and evaluated at least once before 30 months of age.

- If (1) abnormal or (2) normal, but failed prior ABR, or (3) normal, but infant has risk factors, may be referred to an ENT specialist before pursuing ABR.

5. If OAEs abnormal for one or both ears, perform a diagnostic click-evoked ABR via air conduction (can be completed at same or subsequent visit):

   a. Obtain a 70 or 75 dB nHL response to click stimulus to assess the latency and morphology of waves I, III, V, I-III, III-V, and I-V.
   b. Obtain a 30 or 35 dB nHL response to click stimulus to assess the latency and morphology of wave V.

In evaluating absolute and interpeak latencies, the use of age-appropriate norms is recommended.

- If normal and infant has passed diagnostic OAE, audiologist may choose to stop testing. Infants who are not identified with hearing loss, but have one or more risk factors, should be evaluated at least once before 30 months of age.
- If (1) abnormal, or (2) normal, but failed prior diagnostic OAE, perform frequency-specific ABR.

2. Incorporate an immittance battery with caution. For infants under approximately four months of age, multifrequency testing is most appropriate, but nominative data are lacking. For infants older than four months, the immittance battery becomes more reliable and valid.

1. Risk factors for use with neonates or infants (29 days through 2 years): (1) Parental or caregiver concern regarding hearing, speech, language, and/or developmental delay, (2) family history of permanent childhood hearing loss, (3) stigmata or other findings associated with a syndrome known to include a sensorineural or conductive hearing loss or Eustachian tube dysfunction, (4) postnatal infections associated with sensorineural hearing loss including bacterial meningitis, (5) in utero infections such as cytomegalovirus, herpes, toxoplasmosis, or rubella, (6) neonatal indicators - specifically hyperbilirubinemia at a serum level requiring exchange transfusion, persistent pulmonary hypertension of the newborn associated with mechanical ventilation, and conditions requiring the use of extracorporeal membrane oxygenation, (7) syndromes associated with progressive hearing loss such as neurofibromatosis, osteopetrosis, and Usher’s syndrome, (8) neurodegenerative disorders, such as Hunter’s syndrome, or sensory motor neuropathies, such as Friedreich’s ataxia and Charcot-Marie-Tooth syndrome, (9) head trauma, (10) recurrent or persistent otitis media with effusion for at least three months.

2. Perform an otoscopic evaluation.

3. Obtain acoustic immittance measures using a high frequency probe tone is recommended for seven months and younger.

4. Obtain evoked otoacoustic emissions (TEOAE and/or DPOAE).
6. Perform frequency-specific ABR using unmasked Blackman-gated tone-bursts or tonebursts presented in notched noise:
   
a. Obtain threshold response to a 500 and 4000 (or 2000) Hz tone-burst.
   
b. Consider obtaining threshold response to 2000, 1000, and/or 250 Hz (based on results).

7. Perform a click-evoked ABR via bone conduction.

Infants identified with hearing loss should be referred to an ENT for medical/surgical care, and to a Family Resource Coordinator for enrollment in the Infant Toddler Early Intervention Program (ITEIP). Audiologic monitoring should occur every three months.

Infants who are not identified with hearing loss, but who have one or more risk factors, should be evaluated at least once before 30 months of age.

Sharing Diagnostic Results with Families

1. Recognizing the emotional impact that a diagnosis of hearing loss can have on a family, the audiologist should provide the family with information about the degree of hearing impairment, its potential impact on speech and language development, the treatment options available, as well as the positive impacts of early identification and intervention.

2. Information and test findings should be delivered in a positive manner, with sensitivity to the emotional needs of the parents.

3. Audiologists should provide families with information that addresses, but is not limited to, the following subject areas related to educating parents and families about hearing loss and its impacts. The format of this information should be consistent with the family’s needs and desires, language and cultural needs, and their ability to interpret the information:
   
   - Information regarding the role of the FRC, their scope of responsibility, and how to access their services.
   - Information about how to access parent/family support groups, and support networks in the deaf/hard-of-hearing communities.
   - Information on future diagnostic follow-up and referral to early intervention services.

4. If the family expresses a desire to utilize the services of an FRC, secure parental permission to contact the FRC to facilitate successful follow-up and provide the family with access information. (This information is available through the Lead FRC in the family’s home county.)

5. Recognizing that families may not be ready to absorb all of the information in the initial diagnostic evaluation, the audiologist should arrange further discussions with the family, appropriate to the family’s needs and desires. These follow-up discussions may take the form of additional counseling visits, telephone conversations, or additional counseling coordinated with future clinic visits.
